# 1 Introduction

## Hook

Our complex reality reveals itself as a limit for our compartmentalisation of knowledge, that is why I believe we should increase communication between different fields of science. Moreover, in an interdisciplinarity context, physics as a lot to offer. This work is a personal exercise towards this philosophy.

## Research Aim

What is the impact on the transport of nitrates to non-motile phytoplankton cells (diatoms) in the presence of chemotactic bacteria?

## Objectives

- Quantifying the impact of bacterial chemotaxis on the diatom's nutrient availability.
- Modelling the nutrient transport dynamics: Diffusion Equation with a Consumption term.
- Implementing a numerical solution for the model.
- Analytical results validating the numeric's.
- Qualify which symbiotic relationship exists between bacterium and the diatom.

*Hook w Background*

## 2 Literature Review

### 2.1 Biological Background

#### Overview of Phytoplankton and Their Role in Ecosystems

- Role of phytoplankton in aquatic ecosystems (Contribution to the food chain, O<sub>2</sub> production and CO<sub>2</sub> absorption).
- Importance of Nitrate Nutrients (Phytoplankton growth and nutrient uptake mechanisms, Emergence of competition due to nutrient limitation).

#### Bacterium: Competitors in Nutrient Uptake

- Chemotaxis mechanisms (Foraging strategy for marine (and soil) microorganisms)
- Competition (Chemotactic bacteria are attracted to and consume nitrates, competing with diatoms for nutrient availability).

#### Interaction with Bacteria: Competition for Nitrates and Symbiosis

- Diatoms secrete chemicals that attract bacteria.
- ↗ Optimization of bacterial chemotaxis by diatoms?

## 3 Methodology

### 3.1 From Discrete to Continuum

#### Chemotaxis at an Individual Level

- Discrete and stochastic model.
- Individual trajectory,  $x_j(t)$ .

#### Chemotaxis at a Population Level

- Transition from individual to population-level, discrete to continuum approaches.
- Continuum and deterministic model, diffusion equation with consumption.
- Concentration,  $c(t)$ .

### 3.2 Non-Dimensionalisation

We start from the physical equation, where we have capitalised its magnitudes:

$$\frac{\partial N(\vec{R}, T)}{\partial T} = D \nabla_{\vec{R}}^2 N(\vec{R}, T) - A N(\vec{R}, T) C(\vec{R}, T) \quad (1)$$

These quantities represent the real, laboratory measures:  $\vec{R}$  is the position vector relative to the diatom,  $T$  is time,  $D$  is the diffusion coefficient,  $N$  &  $C$  are the nutrient and bacterial concentration respectively, and  $A$  is the bacterial consumption rate. Now, we introduce the following variables changes, to obtain a dimensionless equation:

$$\left\{ \vec{R} = L \vec{r}, \quad T = \frac{L^2}{D} t, \quad N = \frac{n}{L^3}, \quad C = \frac{c}{L^3}, \quad A = DL \alpha \right\} \quad (2)$$

Where the set of lowercase variables (like  $n$  or  $\alpha$ ) are the dimensionless equivalent of the capitalised variables. Whereas  $L$  represents the characteristic length of the system (for example, the system's or diatom's size),  $\frac{L^2}{D}$  is the time unit of the system, meaning the time it takes for a nutrient to diffuse through  $L$ . Replacing these (2) into the equation (1), we obtain the new equation (3) which is ideal for numerical simulations.

$$\frac{\partial n(\vec{r}, t)}{\partial t} = \nabla_{\vec{r}}^2 n(\vec{r}, t) - \alpha n(\vec{r}, t) c(\vec{r}, t) \quad (3)$$

## 4 Results

### 4.1 One-Dimensional Model

#### 4.1.1 Diffusion With Consumption

##### Different Bacterial Concentrations

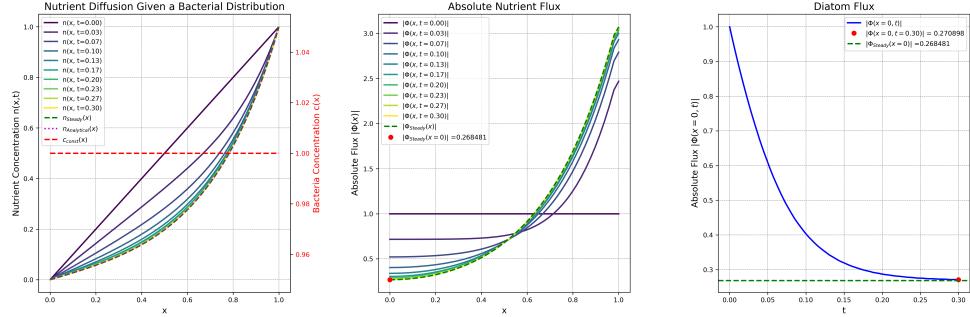

Figure 1: Constant Bacterial Concentration Profile, with Analytical Solution.

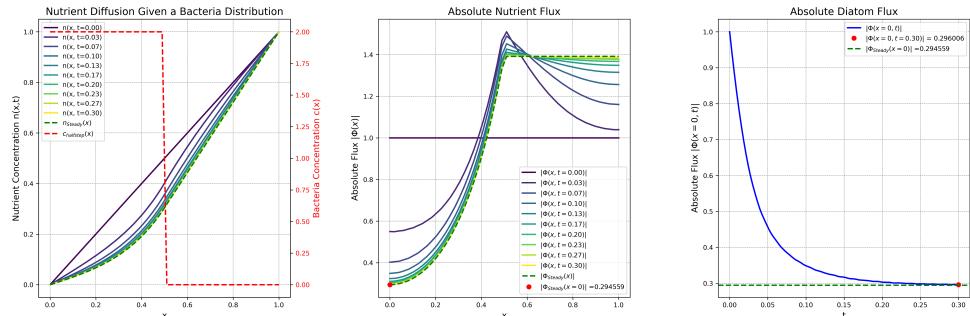

Figure 2: Half-Step Bacterial Concentration Profile.

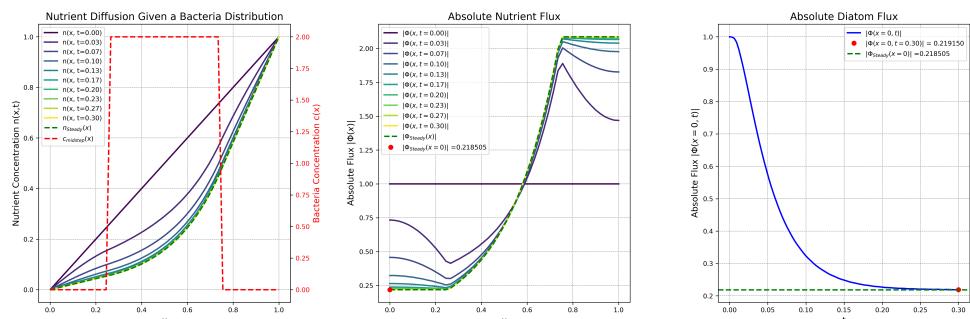

Figure 3: Mid-Step Bacterial Concentration Profile.

*¿Different Diffusion Coefficients?*

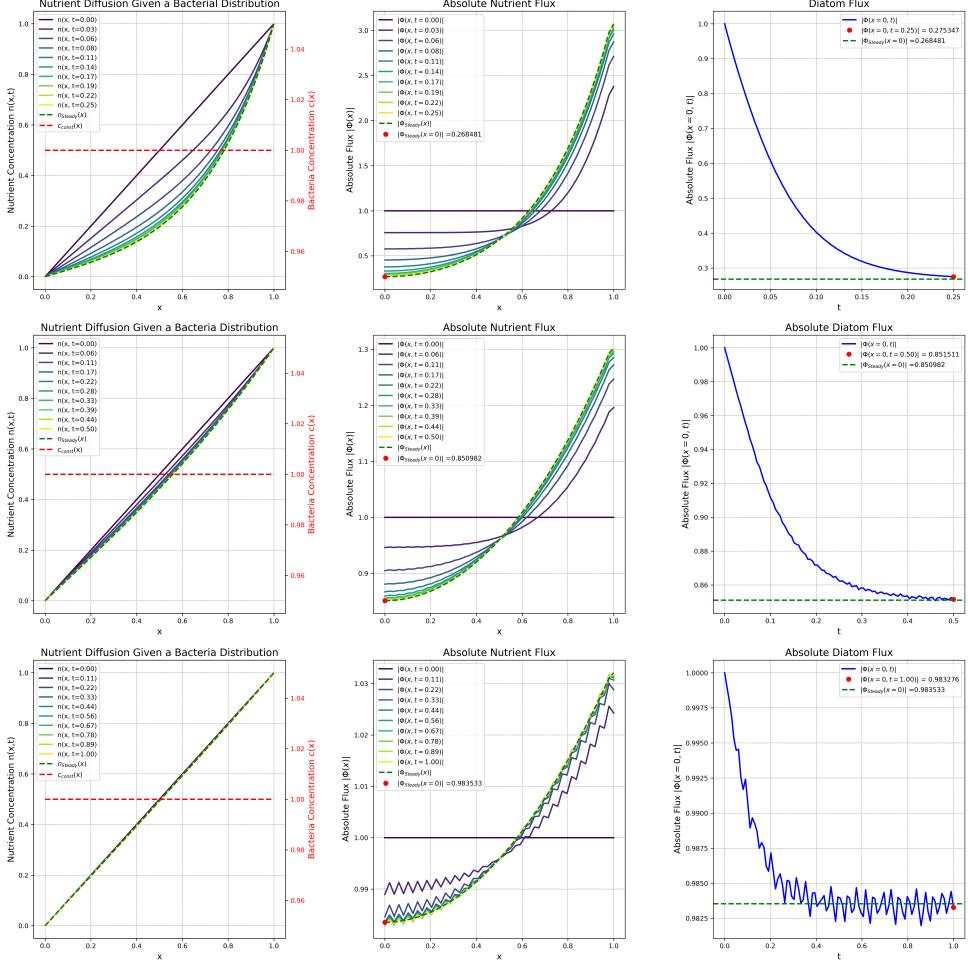

Figure 4: Comparing Different Diffusion-Consumption Ratios.

### Diatom's FluxMaps, Generalising Results for Step & Exponential Concentrations

Concentration profile described by a midstep with varying starting positions ( $x_0$ ) and lengths ( $l$ ), with the restriction  $x_0 + l \leq L$ .

$$c_{\text{midstep}}(x; x_0, l) = \begin{cases} \frac{1}{l} & \text{if } x_0 \leq x \leq x_0 + l, \\ 0 & \text{otherwise.} \end{cases} \quad (4)$$

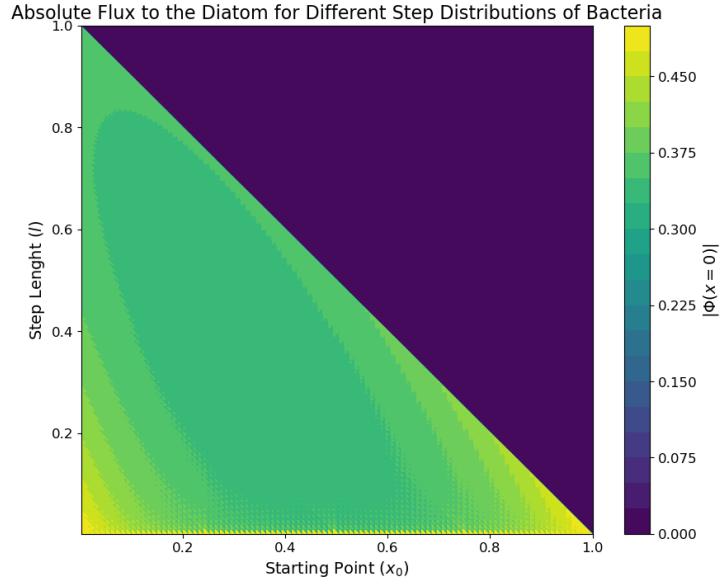

Figure 5: Flux Map for Midstep Concentration Profile.

Concentration profile described by an exponential with varying slope.

$$c_{\text{exp}}(x; \delta) = \frac{1}{\delta L} \frac{e^{-\frac{x}{\delta L}}}{1 - e^{-\frac{1}{\delta}}} \quad (5)$$

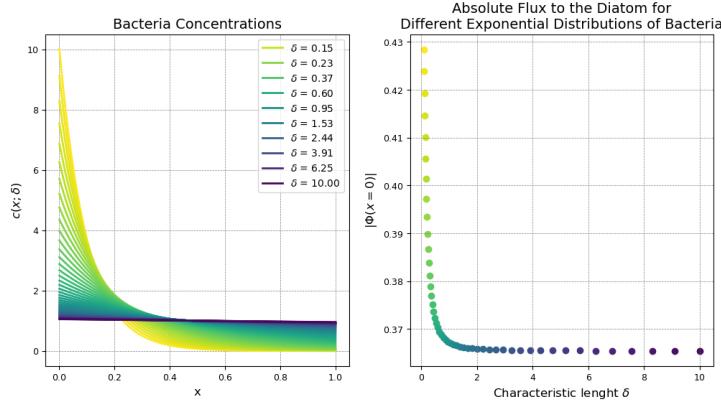

Figure 6: Flux Map for Exponential Concentration Profile.
